Abstract: The combined effect of magnetic field dependent (MFD) viscosity and non-uniform basic temperature profiles on the onset of thermomagnetic convection in a horizontal ferrofluid layer is studied analytically using linear stability theory. The lower and upper boundaries of the ferrofluid layer are assumed to be rigid by prescribing uniform heat flux condition at the lower boundary and a general thermal condition at the upper boundary. The Galerkin technique is used to find the eigenvalues as this technique is found to be more convenient to tackle different forms of basic temperature profiles. The results indicate that the basic cubic temperature profiles have a profound influence on the stability characteristics of the system and can be effectively used to either suppress or augment the onset of thermomagnetic convection. Results show that the conductive effect of non-steady conditions within the fluid layer does play a stabilizing state. It is observed that the effect of magnetic number, nonlinearity of the fluid magnetization is to hasten, while an increase in the magnetic field dependent viscosity parameter and Biot number is to delay the onset of ferroconvection.

Keywords: Non-Uniform-Basic-Temperature Profiles, Ferroconvection, Magnetic-Field-Density Viscosity, Galerkin Technique, Darcy-Rayleigh Number, General Thermal Boundaries

1. Introduction

Ferrofluids or magnetic fluids are commercially manufactured colloidal liquids usually formed by suspending mono domain nanoparticles (their diameter is typically 3~10 nm) of magnetite in non-conducting liquids like heptane, kerosene, water etc and they are also called magnetic nanofluids. These fluids get magnetized in the presence of an external magnetic field and due to their both liquid and magnetic properties they have emerged as reliable materials capable of solving complex engineering problems. An authoritative introduction to this fascinating subject and along with the important applications of these fluids in many practical problems is well documented in the literature [1-5]. It is also recognized that these fluids have promising potential for heat transfer applications in electronics, micro and nano-electro-mechanical systems (MEMS and NEMS), and air-conditioning and ventilation systems for details see Ganguly et al. [6].

The magnetization of ferrofluids depends on the magnetic field, temperature, and density. Hence, any variations of these quantities induce change of body force distribution in the fluid and eventually give rise to convection in ferrofluids in the presence of a gradient of magnetic field. There have been numerous studies on thermal convection in a ferrofluid layer called ferroconvection analogous to Rayleigh-Benard convection in ordinary viscous fluids. Finlayson [7] was the first to study thermal convective instability in a layer of ferrofluid heated from below in the presence of a uniform vertical magnetic field. Since then several studies have been undertaken in this direction to understand heat transfer in ferrofluids [8-18]. Sunil and Mahajan [19] have performed nonlinear stability analysis for a magnetized ferrofluid layer heated from below for the stress-free boundaries case, while Nanjundappa and Shivakumara [20] have investigated the effects of different kinds of velocity and temperature boundary conditions on the onset of ferroconvection in an initially quiescent ferrofluid layer. Recently, thermal convection of ferrofluids in the presence of a uniform vertical magnetic field with the boundary temperatures modulated...
The effect of MFD viscosity on the onset of ferroconvection in a rotating ferrofluid layer is discussed by Vaidyanathan et al. [21], with or without dust particles by Sunil et al. [22] and the non-linear stability analysis has also been performed by Sunil et al. [23]. Recently, Nanjundappa et al. [24] have investigated the effect of MFD viscosity on the onset of convection in a ferromagnetic fluid layer in the presence of a vertical magnetic field by considering the bounding surfaces are either rigid-ferromagnetic or stress-free with constant heat flux conditions. In this sense more investigations have been taken place see [25]-[28].

The intent of the present paper is to study coupled Bénard-Marangoni ferroconvection in a ferrofluid layer in the presence of a uniform vertical magnetic field with magnetic field dependent viscosity. The lower boundary is rigid with fixed temperature, while the upper non-deformable free boundary is subjected to temperature dependent surface tension forces and a general thermal boundary condition on the perturbation temperature is imposed. The study helps in understanding control of ferroconvection by magnetic field dependent viscosity, which is useful in many heat transfer related problems particularly in materials science processing. The resulting eigenvalue problem is solved numerically by employing the Rayleigh-Ritz method with Chebyshev polynomials of the second kind as trial functions.

The paper is organized as under. Section 2 is devoted to the formulation of the problem. The method of solution is discussed in Section 3. In Section 4, the numerical results are discussed and some important conclusions follow in Section 5.

2. Mathematical Formulation

The present paper considered Boussinesq ferrofluid layer of thickness \( d \) with no lateral boundaries and uniform magnetic field \( H_0 \) acting normal to the boundaries. The lower and the upper boundaries are maintained at constant but different temperatures \( T_0 \) and \( T_1 (<T_0) \) respectively. A Cartesian co-ordinate system \((x, y, z)\) is used with the origin at the lower boundary and the z-axis vertically upward. Gravity acts in the negative z-direction, \( \vec{g} = -g \hat{k} \), where \( \hat{k} \) is the unit vector in the z-direction. The layer is bounded below by a rigid surface while the free surface which is subjected to temperature dependent surface tension forces is assumed to be flat and non-deformable. The fluid density \( \rho \) is assumed to vary linearly with temperature in the form.
where $\alpha_t$ is the thermal expansion coefficient and $\rho_0$ is the density at $T = T_0$.

In the study of ferroconvection, we have to solve the Maxwell equations simultaneously with the balance of mass, linear momentum and energy. Since the fluid is assumed to be electrically not conducting, the Maxwell equations reduce to

$$\nabla \cdot \vec{B} = 0 \quad (2)$$

$$\nabla \times \vec{H} = 0 \quad (3)$$

In view of Eq. (3), the magnetic field expressed by a scalar potential $\vec{H} = \nabla \varphi$.

Further $\vec{B}, \vec{M}$ and $\vec{H}$ are related by

$$\vec{B} = \mu_0 (\vec{M} + \vec{H}) \quad (5)$$

By assuming that the magnetization is aligned with the magnetic field, but allow dependence on the magnitude of magnetic field as well as on the temperature, thus

$$M = [M_0 + \chi (H - H_0) - K(T - T_0)] \{\mu / H\} \quad (6)$$

The momentum equation is

$$\rho \left[ \frac{\partial \vec{q}}{\partial t} + (\vec{q} \cdot \nabla) \frac{\partial \varphi}{\partial t} \right] = -\nabla p + \rho \vec{g} + \mu_0 (\vec{M} \cdot \nabla) \vec{H} + 2\nabla \cdot [\eta \vec{D}] \quad (7)$$

The fluid is assumed to be incompressible having variable viscosity. Experimentally, it has been demonstrated that the magnetic viscosity has got exponential variation, with respect to magnetic field (Rosenswieg [19]). As a first approximation, for small field variation, linear variation of magnetic viscosity has been used in the form

$$\eta = \eta_0 (1 + \delta \cdot \vec{B})$$

where $\delta$ is the variation coefficient of magnetic field dependent viscosity and is considered to be isotropic (Vaidyanathan et al. [21]), $\eta_0$ is taken as viscosity of the fluid when the applied magnetic field is absent.

Neglecting viscous dissipation, the energy equation is

$$\nabla \cdot \vec{q} = 0 \quad (9)$$

The basic state is quiescent and is given by

$$\vec{q} = 0, \quad p = p_b(z), \quad \frac{\partial T_b}{\partial z} = f(z), \quad \vec{H}_b = \left[ H_0 - \frac{K \beta z}{1 + \chi} \right] \hat{k}, \quad \vec{M}_b = \left[ M_0 + \frac{K \beta z}{1 + \chi} \right] \hat{k} \quad (10)$$

where, $\hat{k}$ is the unit vector in the z-direction and $f(z)$ is the basic temperature gradient, such that

$$\int f(z) dz = \frac{\Delta T}{d}$$

The stability of the basic state can be analyzed by introducing the following perturbations:

$$\vec{q} = \vec{q}', \quad p = p_b(z) + p', \quad \eta = \eta_b(z) + \eta', \quad T = T_b(z) + T', \quad \vec{H} = \vec{H}_b(z) + \vec{H}', \quad \vec{M} = \vec{M}_b(z) + \vec{M}' \quad (11)$$

where, $\vec{q}', \vec{p}', \eta', T', \vec{H}'$ and $\vec{M}'$ are perturbed variables and are assumed to be small.

Substituting Eq. (11) into Eq. (2) and using Eqs. (5) and (6), the following obtained (after dropping the primes)

$$H_x + M_x = (1 + M_0 H_0) H_x, \quad H_y + M_y = (1 + M_0 H_0) H_y, \quad H_z + M_z = (1 + \chi) H_z - K T \quad (12)$$

where, $(H_x, H_y, H_z)$ and $(M_x, M_y, M_z)$ are $(x, y, z)$ components of perturbed magnetic field and magnetization respectively. In obtaining the above equations, it is assumed that $K \beta d \ll (1 + \chi) H_0$.

Substituting Eq. (11) into Eq. (7) and linearizing, we obtain in components (after neglecting the primes)
\[ \rho_0 \frac{\partial u}{\partial t} = -\frac{\partial p}{\partial x} + \eta_0 \left[ 1 + \mu_0 \delta (M_0 + H_0) \right] \nabla^2 u + \mu_0 (M_0 + H_0) \frac{\partial H_x}{\partial z} \]  
\[ \rho_0 \frac{\partial v}{\partial t} = -\frac{\partial p}{\partial y} + \eta_0 \left[ 1 + \mu_0 \delta (M_0 + H_0) \right] \nabla^2 v + \mu_0 (M_0 + H_0) \frac{\partial H_y}{\partial z} \]  
\[ \rho_0 \frac{\partial w}{\partial t} = -\frac{\partial p}{\partial z} + \rho_0 \alpha \beta T + \eta_0 \left[ 1 + \mu_0 \delta (M_0 + H_0) \right] \nabla^2 w + \mu_0 (M_0 + H_0) \frac{\partial H_z}{\partial z} - \mu_0 K f(z) H_z + \frac{\mu_0 K^2 f(z) T}{1 + \chi} \]  

Differentiating Eqs. (13) and (14) partially with respect to \( x \) and \( y \) respectively and adding, obtained following
\[ \nabla^2 p = -\rho_0 \alpha \beta \left( \nabla \cdot \vec{H} \right) - \mu_0 K f(z) \frac{\partial H_z}{\partial z} + \frac{\mu_0 K^2 f(z) \frac{\partial T}{\partial z}}{1 + \chi} \]  

where \( \nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \) is the horizontal Laplacian operator. Eliminating the pressure term from Eq. (15), using Eq. (16), finally
\[ \left[ \rho_0 \frac{\partial}{\partial t} - \eta_0 \left[ 1 + \delta \mu_0 (M_0 + H_0) \right] \right] \nabla^2 w = -\rho_0 \alpha \beta \left( \nabla \cdot \vec{H} \right) - \mu_0 K f(z) \frac{\partial H_z}{\partial z} + \frac{\mu_0 K^2 f(z) \frac{\partial T}{\partial z}}{1 + \chi} \]  

As before, substituting Eq. (11) into Eq. (8) and linearizing (after neglecting primes)
\[ \rho_0 C_0 \frac{\partial T}{\partial t} - \mu_0 K T_0 \frac{\partial \phi}{\partial z} = \left( \rho_0 C_0 - \frac{\mu_0 K^2 T_0}{1 + \chi} \right) W f(z) + k_t \nabla^2 T \]  

where \( \rho_0 C_0 = \rho_0 C_{\nu, H} + \mu_0 K H_0 \).

Finally, Eqs. (2) and (3), after using Eqs. (12) and (13), yield (after neglecting primes)
\[ \left( 1 + \frac{M_0}{H_0} \right) \nabla^2 \phi + (1 + \chi) \frac{\partial^2 \phi}{\partial z^2} - K \frac{\partial T}{\partial z} = 0 \]  

Since by assuming that the principle of exchange of stability is valid, the normal mode solution in the form
\[ \{ w, T, \phi \} = \{ W, \Theta, \Phi \} (z) \exp[i(\xi x + \eta y) + \omega t] \]  

where \( \xi \) and \( \eta \) are wavenumbers in the \( x \) and \( y \) directions, \( W(z), \Theta(z), \Phi(z) \) are the amplitude of \( z \)-component of perturbation velocity, perturbation temperature, perturbation magnetization and \( \omega \) is the growth rate. Substituting Eq. (20) in Eqs. (17)- (19) and non-dimensionalizing the quantities in the form
\[ (x^*, y^*, z^*) = \left( \frac{x}{d}, \frac{y}{d}, \frac{z}{dz} \right), \quad W^* = \frac{d}{V} W, \quad t^* = \frac{V}{d^2} t, \quad \Theta^* = \frac{\kappa}{\beta} \frac{\Theta}{d} \quad \Phi^* = \frac{1 + \chi}{K} \frac{\kappa}{\beta} \frac{\Phi}{d}, \]  

\[ \delta^* = \mu_0 (M_0 + H_0) \delta, \quad f(z)^* = \frac{1}{B} f(z) \left( \beta = \frac{-\Delta T}{d} \right) \]

obtained (after ignoring the asterisks)
\[ \left[ (1 + \Lambda) \left( (D^2 - a^2) - \omega \right) \right] \]  
\[ \left( D^2 - a^2 - \frac{Pr \omega}{\Theta} \right) \Theta - Pr M_a \omega D \Phi = \left( (1 - M_a) \right) f(z) W \]  
\[ \left( D^2 - a^2 M_3 \right) \Phi - D \Theta = 0 \]

\( f(z) \) is the non-dimensional temperature gradient such that \( \int_0^1 f(z) dz = 1 \). The boundary conditions for the perturbed non-dimensional variables take the form

\[ (D^2 - a^2) \Theta - a^2 \Phi = (1 - M_3) f(z) W \]  

\[ (D^2 - a^2 M_3) \Phi - D \Theta = 0 \]
\[ W = DW = D\Theta = \Phi = 0 \text{ at } z = 0 \quad (25) \]
\[ W = DW = D\Theta + Bi \Theta = \Phi = 0 \text{ at } z = 1 \quad (26) \]

The case \( Bi = 0 \) and \( Bi \rightarrow \infty \) respectively correspond to constant heat flux and isothermal conditions at the upper boundary.

The Boussinesq approximation is assumed (except for the surface tension) to be varying with the temperature. The steady state temperature profile reveals the form of a cubic equation within the fluid layer due to the existence of the non-steady conditions (Pearson (1958), Perea-García (1991) and Dupont (1992)), given by

\[ T_0 = T_{0u} - a_1(z-d) - a_2(z-d)^2 - a_3(z-d)^3, \]

where \( T_{0u} \) is the temperature at the upper free surface of the fluid layer and \( a_i, i = 1,2,3 \) is the polynomial coefficient of the transient temperature profile. In non-dimensional form, the \( f(z) \) in this case is given by

\[ f(z) = a_1^* + 2a_2^*(z-1) + 3a_3^*(z-1)^2. \]

The special case \( a_1^* = 1, a_2^* = 0 \) and \( a_3^* = 0 \) recovers the classical linear basic state temperature distribution. The different temperature gradients studied in this paper are listed in Table 1.

### 3. Method of Solution

Equations (22)-(24) together with boundary conditions given by Eqs. (25) – (26) constitute an eigenvalue problem with thermal Rayleigh number \( R_t \) being an eigenvalue. Accordingly, \( W, \Theta \) and \( \Phi \) are written as

\[ W(z) = \sum_{i=1}^{n} A_i W_i(z), \Theta(z) = \sum_{i=1}^{n} B_i \Theta_i(z) \text{ and } \]
\[ \Phi(z) = \sum_{i=1}^{n} C_i \Phi_i(z) \quad (27) \]

where \( A_i, B_i \) and \( C_i \) are unknown constants to be determined. The basis functions \( W_i(z), \Theta_i(z) \) and \( \Phi_i(z) \) are generally chosen such that they satisfy the corresponding boundary conditions. Substituting Eq. (27) into Eqs. (22)-(24), multiplying the resulting momentum Eq. (22) by \( W_j(z) \), energy Eq. (23) by \( \Theta_j(z) \) and the magnetic potential Eq. (24) by \( \Phi_j(z) \); performing the integration by parts with respect to between \( z = 0 \) and \( z = 1 \) and using the boundary conditions (25) – (26), the following system of linear homogeneous algebraic equations are obtained:

\[ C_{ji} A_i + D_{ji} B_i + E_{ji} C_i = 0 \quad (28) \]
\[ F_{ji} A_i + G_{ji} B_i = 0 \quad (29) \]
\[ H_{ji} B_i + I_{ji} C_i = 0. \quad (30) \]

The coefficients \( C_{ji} - I_{ji} \) involve the inner products of the basis functions and are given by

\[ C_{ji} = (1 + A) < D^2 W_j D^2 W_i > + 2a^2 D W_j D W_i + a^4 W_j W_i > \]
\[ D_{ji} = -a^2 R_t [ < W_j \Theta_i > + M_l < f(z) W_j \Theta_i > ] \]
\[ E_{ji} = a^2 R_m < f(z) W_j D \Phi_i > \]
\[ F_{ji} = -< f(z) \Theta_j W_i > \]
\[ G_{ji} = < D \Theta_j D \Phi_i > + a^2 < \Theta_j \Theta_i > + Bi \Theta_j(1) \Theta_i(1) \]
\[ H_{ji} = -< D \Phi_j \Theta_i > \]
\[ I_{ji} = < D \Phi_j D \Phi_i > + a^2 M_3 < \Phi_j \Phi_i > \quad (31) \]

where the inner product is defined as \( < \cdots > = \frac{1}{d} \int (\cdots) dz \).

The above set of homogeneous algebraic equations can have a non-trivial solution if and only if

\[ \begin{vmatrix} C_{ji} & D_{ji} & E_{ji} \\ F_{ji} & G_{ji} & 0 \\ H_{ji} & I_{ji} \end{vmatrix} = 0. \quad (32) \]

The eigenvalue has to be extracted from the above characteristic equation. For this, selected the following trial functions

\[ W_i = (z^4 - 2z^3 + z^2) T_i, \quad \Theta_i = z^2(1 - 2z/3) T_i \quad \Phi_i = (z^2 - z)(z - 2) T_i \quad (33) \]

where, \( T_i \) are the Chebyshev polynomials of the second kind, such that \( W_i, \Theta_i \) and \( \Phi_i \) satisfy the corresponding boundary conditions except, \( (1 + A) D^2 W + Ma^2 \Theta = D \Theta + Bi \Theta = 0 \) at \( z = 1 \) but the residuals from the equations are included as residuals from the differential equations. Equation (32) leads to a relation
involving the physical parameters $R_1$, $\Lambda$, $M_1$, $M_3$, $Bi$, $a_1^*$, $a_2^*$, $a_3^*$, and $a$ in the form

$$f(R_1, \Lambda, Bi, M_1, M_3, a_1^*, a_2^*, a_3^*, a) = 0. \quad (34)$$

The critical value of $R_1$ (i.e., $R_{c_1}$) is determined numerically with respect to $a$ for different values of $\Lambda$, $M_1$, $M_3$, $Bi$, $a_1^*$, $a_2^*$, and $a_3^*$.

### 4. Results and Discussion

The critical stability parameters are obtained numerically using the Galerkin method with general types of boundary conditions. Besides, analytical solutions are also obtained using a regular perturbation technique when the boundaries are kept at constant heat flux conditions and the results are compared with those obtained numerically. A discussion on the results is made in the following sub-sections.

#### 4.1. Numerical Solution for General Thermal Conditions

The linear stability theory is used to investigate the effect of MFD viscosity and non-uniform basic temperature profile on the onset of ferroconvection in a horizontal ferrofluid in the presence of a uniform vertical magnetic field. The lower and upper boundaries of the ferrofluid layer are assumed to be rigid by prescribing uniform heat flux condition at the lower boundary and a general thermal condition at the upper boundary. The resulting eigenvalue problem is solved numerically using the Galerkin method. First checked the numerical procedure used by comparing the critical Rayleigh number and the corresponding wave number with those of Sparrow et al. [34] for an ordinary viscous fluid. It is observed that six terms (i.e., $N = 6$) in the series expansion of Eq. (34) are required to obtain convergent results.

Table 2 shows the comparison of our results with those of Sparrow et al. [36] for different values of $Bi$ under the limiting case of $M_1 = M_3 = 0$, $\Lambda = 0$, $a_1^* = 1$, $a_2^* = 0$ and $a_3^* = 0$ (i.e., ordinary viscous fluid). From the table it is evident that there is an excellent agreement between the results of the present study and the previously published ones. This verifies the applicability and accuracy of the method used in solving the problem.

![Figure 1](image-url) The variation of $R_c$ as a function of $\Lambda$ for different non-linear temperature profiles with two values of $Bi$ when $M_1 = 2$ and $M_3 = 1$. 

The critical Rayleigh numbers $R_{nc}$ and the corresponding wave numbers $a_c$ obtained for different values of $\Lambda$, $Bi$, $M_1$ and $M_3$ are presented graphically in Figures 1-3. Figure 1 shows the variation of critical Rayleigh number $R_{nc}$ as a function of MFD viscosity parameter $\Lambda$ for different types of non-uniform basic temperature profile with $M_1 = 2$ and $M_3 = 1$. From the figure it is evident that the variation of $Bi$ from 0 to 2 significantly increase the critical Rayleigh numbers in both the cases of velocity boundary conditions considered; the least being for $Bi = 0$ and the highest values correspond to those for $Bi = 2$. Thus the system is found to be more unstable for the upper heat insulating boundary as compared to isothermal condition at the upper boundary. This behavior is not surprising as the nature of the upper boundary changes drastically from an insulated surface to a conductive boundary with an increase in the value of $Bi$. It is evident that with an increase in the value of $Bi$ the temperature perturbations will not grow so easily and therefore higher values of $R_{nc}$ are needed for the onset of ferroconvection. Further, the critical Rayleigh number $R_{nc}$ increase with an increase in the MFD viscosity parameter $\Lambda$ and thus it has a stabilizing effect on the system. That is, the effect of increasing $\Lambda$ is to delay the onset of ferroconvection. Besides, for a fixed value of $Bi$, the critical Rayleigh numbers (i.e., $R_{nc1}$) for cubic temperature profile (i.e., Model 3) with $a_1^* = 0 = a_2^*$ and $a_3^* = 1$ is shown to be the most stabilizing of all the considered types of temperature profiles, that is, $R_{nc2} (= R_{nc3}) < R_{nc1} < R_{nc4} < R_{nc3}$.

![Figure 2](image1.png)  
*Figure 2. The variation of $R_{nc}$ as a function of $\Lambda$ for different non-linear temperature profiles with two values of $M_1$ when $Bi = 2$ and $M_3 = 1$.*

![Figure 3](image2.png)  
*Figure 3. The variation of $R_{nc}$ as a function of $\Lambda$ for different non-linear temperature profiles with two values of $M_1$ when $Bi = 2$ and $M_3 = 2$.*
The measure of nonlinearity of fluid magnetization, denoted through the parameter \( M_3 \), on the onset of ferroconvection is depicted in Figure 2. The curves of \( R_v \) versus \( \Lambda \) shown in Figure 3 for different values of \( M_3 \) with non-uniform temperature profiles when \( Bi = 2 \) and \( M_1 = 2 \), demonstrate that increasing \( M_3 \) has a destabilizing effect on the system. Nevertheless, the destabilization due to increase in the nonlinearity of the fluid magnetization is only marginal. This may be attributed to the fact that a higher value of \( M_3 \) would arise either due to a larger pyromagnetic coefficient or larger temperature gradient. Both these factors are conducive for generating a larger gradient in the Kelvin body force field, possibly promoting the instability. Similar is the situation in the case of critical wave numbers and the same is evident from Figure 3.

### 4.2. Solution by Regular Perturbation Technique

Since the critical wave number is negligibly small for constant-flux thermal boundary conditions (i.e., \( D\Theta = 0 \) at \( z = 0, 1 \)), the eigenvalue problem is also solved analytically using regular perturbation technique with wave number \( a \) as a perturbation parameter. Accordingly, \( W \), \( \Theta \) and \( \Phi \) are expanded in powers of \( a^2 \) as

\[
(W, \Theta, \Phi) = (W_0, \Theta_0, \Phi_0) + a^2(W_1, \Theta_1, \Phi_1) + \cdots. \tag{35}
\]

Substituting Eq. (35) into Eqs. (22)-(24) and also in the boundary conditions, and collecting the terms of zeroth order in \( a \), the following obtained

\[
D^3 W_0 = 0 \tag{36}
\]
\[
D^2 \Theta_0 = -W_0 \tag{37}
\]
\[
D^2 \Phi_0 = -D\Theta_0 \tag{38}
\]

with the corresponding boundary conditions

\[
W_0 = D W_0 = 0 = D\Theta_0 = \Phi_0 \quad \text{at} \quad z = 0, 1. \tag{39}
\]

The solution to the zero-th order equations is found to be

\[
W_0 = 0, \Theta_0 = 1 \text{ and } \Phi_0 = 0. \tag{40}
\]

The first order equations in \( (a^2) \) are then

\[
D^3 W_1 = R_v (1 + M_1) \tag{41}
\]
\[
D^2 \Theta_1 = 1 - W_1 \tag{42}
\]
\[
D^2 \Phi_1 = D\Theta_1 \tag{43}
\]

with the boundary conditions

\[
W_1 = D W_1 = \Phi_1 = D\Theta_1 = 0. \tag{44}
\]

The general solution of Eq. (41) is given by

\[
W_1 = c_1 \cosh(\sigma_e z) + c_2 \sinh(\sigma_e z) + c_3 + c_4 z - R_v (1 + M_1) z^2 / 2\sigma_e^2 \tag{45}
\]

where the arbitrary constants \( c_1 - c_4 \) are to be determined using the non-uniform temperature profiles and they are given by

- Model 1: Linear temperature profile
- Model 2: Inverted parabolic temperature profile
- Model 3: Parabolic temperature profile
- Model 4: Cubic 1
- Model 5: Cubic 2

(i) rigid-rigid boundaries

\[
c_1 = \frac{R_v (1 + M_1)(1 + \cosh \sigma_e)}{2\sigma_e^2 \sinh \sigma_e}, \quad c_2 = -\frac{R_v (1 + M_1)}{2\sigma_e^3}, \quad c_3 = -c_1, \quad c_4 = -\sigma_e c_2. \tag{46}
\]

(ii) rigid-free boundaries

\[
c_1 = -\frac{R_v (1 + M_1)[(\sigma_e^2 - 2) \sinh \sigma_e + 2\sigma_e]}{2\sigma_e^4 (\sinh \sigma_e - \sigma_e \cosh \sigma_e)}, \quad c_2 = \frac{R_v (1 + M_1)[(\sigma_e^2 - 2) \cosh \sigma_e + 2]}{2\sigma_e^4 (\sinh \sigma_e - \sigma_e \cosh \sigma_e)}
\]

\[
c_3 = -c_1, \quad c_4 = -\sigma_e c_2. \tag{47}
\]

Integrating Eq. (45) between \( z = 0 \) and \( z = 1 \) and using the boundary condition on temperature, it follows that

\[
1 = \int_0^1 W_1 dz. \tag{48}
\]
Substituting for $W_1$ from Eq. (37) into Eq. (40) and carrying out the integration leads to an expression for the critical Rayleigh number for rigid-rigid and rigid-free boundaries, respectively, in the form

$$R_{ec} = \frac{12\sigma_e^4 \sinh \sigma_e}{(1 + M_1)[\sigma_e^2 \sinh \sigma_e + 12\sinh \sigma_e - 6\sigma_e(1 + \sinh \sigma_e)]}$$

and

$$R_{ec} = \frac{12\sigma_e^4(\sinh \sigma_e - \sigma_e \cosh \sigma_e)}{(1 + M_1)[4\sigma_e(\sigma_e^2 - 6) \sinh \sigma_e + (24 - \sigma_e^4) \cosh \sigma_e + 12(\sigma_e^2 - 2)]}.$$  

It is interesting to check the above relations for some special cases. When $M_1 = 0$ (i.e., ordinary viscous fluid case) then the above equations coincide with those obtained by Shivakumara and Nanjundappa [30].

Letting $\Lambda = 1$ and $\sigma_e \to 0$, Eq. (50) becomes

$$R_c = \frac{720}{1 + M_1}.$$  

and Eq. (50) becomes

$$R_c = \frac{320}{1 + M_1}.$$  

thus recovering the results for non-porous case discussed by Nanjundappa and Shivakumara [17]. Noticed that the above two equations respectively reduce to $R_c = 720$ and $R_c = 320$ when $M_1 = 0$ which are the known exact values for the ordinary viscous fluid layer [25]. From Eqs (51) and (52), it is interesting to note that the nonlinearity of fluid magnetization (i.e., $M_3$) has no effect on the onset of convection; a result which is revealed by numerical computations carried out in the previous section. Since at the onset of convection $\sigma_e = 0$ (very large wave length), one would expect that $M_3$ has no effect on the stability of the system. The numerically computed values of $R_c$ for different values of $M_1$, $Da^{-1}$ and $\Lambda$ with $Bi = 0$ are compared in Table 2 with those obtained using regular perturbation technique. The results so obtained from simple regular perturbation technique coincide exactly with those obtained from time consuming numerical methods and thus provides a justification for the analytically obtained results for prescribed heat flux conditions (i.e. $Bi = 0$). In other words, the solutions obtained analytically are exact. As noticed earlier, increase in the value of $\Lambda$, as well as decrease in $M_1$ is to increase $R_c$ and raises the stability of the system.

The velocity eigenfunction $W(z)$ is presented in Figures 4 and 5 for different values of $M_1$ and $\Lambda$ respectively. As can be seen, increase in the value of MFD viscosity parameter $\Lambda$ (see Figure 4) is to retard the ferrofluid flow and hence their effect is to delay the onset of convection. But increase in the value of magnetic parameter $M_1$ (see Figure 5) is to speed up the ferrofluid flow and hence its effect is to hasten the onset of ferroconvection in a ferrofluid saturated porous layer.

![Figure 4. Velocity Eigen function for two values of $M_1$ when $\Lambda = 0.2$ and $Bi = 0$.](image-url)
5. Conclusions

The linear stability theory is used to investigate the effect of MFD viscosity and non-uniform temperature gradients on the onset ferroconvection in a ferrofluid layer. The lower and upper boundaries of the porous layer are assumed to be rigid by prescribing uniform heat flux condition at the lower boundary and a general thermal condition at the upper boundary. The resulting eigenvalue problem is solved numerically by employing the Rayleigh-Ritz technique.

The following conclusions can be drawn from the present study:

The effect of increase in the value of magnetic field dependent viscosity parameter $\Lambda$ and the Biot number $Bi$ is to delay the onset of ferroconvection, while increase in the value of magnetic number $M_1$ and nonlinearity of magnetization parameter $M_3$ is to advance the onset of ferroconvection.

The parameter $M_3$ has no effect on the stability of the system in the case of constant-flux thermal boundary conditions (i.e., $Bi=0$).

The numerically and analytically obtained results for the case of constant-flux thermal boundary conditions coincide with each other indicating that the critical stability parameters obtained from the analytical formula are exact.
